Observation of Student Teacher (Form 1)

Student	Haaris Jamil	Date	30th October, 2026
Class / Year level	Year 10	Subject	Science

Pre-Observation Discussion

Student teacher completes the first column and discusses prior to lesson observation.

Pre-Observation		Evidence from Observation
What exactly do you want observed and why? What do you want the observer to notice?	Following the feedback from the evaluative visitor, I would like the observation to focus on my use of students' names and the relationships evident in my interactions with them. I already make a conscious effort to use names, so I would value specific observations of how consistently and naturally I do this when questioning, acknowledging contributions and offering help. Please also notice how I listen and respond to students, distribute my attention across the class, and encourage quieter or less confident learners to contribute.	Haaris consistently uses individual student names when communicating with the class. His respectful demeanour when talking with the students creates a calm, purposeful environment. Students are challenged with being asked to make predictions and relate experimental findings to the physics concepts being taught. Students readily provide answers and statements that are expanded upon should the answers be incorrect. The teacher consistently moving from group to group enables all students to have the opportunity to show their understanding.
What outcomes are you expecting?	I want students to feel recognised and comfortable asking questions, sharing their thinking and seeking help. I would like feedback on whether my interactions are respectful, encouraging and responsive, and whether I connect with a broad range of students rather than mainly those who readily participate. Specific examples of my interactions and students' responses will help me identify what is working and what I could improve.	Students are steadily becoming more vocal during whole-class teaching sessions. Some students are keen to share their experiences, while others who are so vocal or confident in supplying answers have the opportunity during small group practical sessions.

Post-Observation Discussion

Notes can be added through the lesson by the observer and expanded on during the discussion.

Students

- What are the intended learning outcomes for this lesson or unit of work?
- What information do you have about how students achieved the intended learning outcomes?

- What are their remaining misunderstandings? / What are the next steps in learning?

Teaching

Review pre-observation criteria	
Student teacher reflection of the observation focus	Lee's feedback confirmed that I used students' names consistently and that my interactions with them were respectful. He also noticed that moving between groups gave quieter students opportunities to show their understanding without having to speak in front of the whole class. That was useful to hear, because I had found it difficult to keep the group who had missed the previous lesson on task. I want to keep using those small-group conversations to hear from students who don't usually volunteer an answer, and make it easier for students who have been away to rejoin the lesson.
Observer's key pieces of evidence of what was noticed	The success of building circuits stimulating student interest and enjoyment
Areas of strength	Purposeful teaching throughout lesson
Agreed goal for next steps	Engage students further using 'student based' contexts that explore learning objectives. E.g a previous example was relating resistance to electronic volume control in speakers and temperature control in ovens

Student Teacher Evaluation

Student evaluation of lesson taught and observation discussion	Six students had missed the previous practical, and helping them catch up took longer than I expected. I demonstrated the planned resistance investigation rather than having students carry it out themselves. From the graph and class discussion, I think we reached the main idea: the ratio of voltage to current was constant for the component we tested, and we identified that ratio as its resistance. We also considered how changing resistance affects current. The discussion gave me some evidence of understanding, but it did not tell me how securely each student understood it. Next time, I would prepare a shorter catch-up task, make time for students to test the effect of changing resistance themselves, and use a brief individual question to check their understanding. I would also build on Lee's suggestion by using a familiar example, such as volume control, and asking students to connect it to what they observed in the circuit.
